

Requirements & MVP

Purpose: connect modeled user needs to a small set of requirements and observable acceptance criteria.

Author: Jalpa Parmar

Version 1.0 | 23 September 2026

Independent portfolio prototype. Synthetic scenario; no employer or customer data.

User needs and MVP boundary

Support needs ownership and progress. Engineering needs a useful handoff. QA needs validation ideas. Product and delivery leaders need visibility into patterns and blockers. These needs are hypotheses for the portfolio scenario, not findings from interviews.

The MVP covers queue review, recommendations, human decisions, engineering work, status, digests and feedback. I left real integrations, production AI, customer data, authentication, durable storage, automated communication, release automation and SLA prediction out of scope.

Functional requirements

ID	Requirement	Acceptance criterion
FR-01	Find and inspect a support request.	Search and filters narrow the synthetic queue; the original request remains visible.
FR-02	Prepare structured context.	Show summary, category, priority, component and validation ideas with a clear simulation disclosure.
FR-03	Review before creating work.	A person can edit summary, priority, queue and owner. Reading or accepting a suggestion alone creates no work.
FR-04	Return incomplete requests.	A return requires an information note, changes support status and creates no engineering item.
FR-05	Confirm ownership.	Show a routing rationale and allow override before the final approval.
FR-06	Create work once per request.	Approval creates one linked item. Repeated approval is rejected within the session.

Tracking and feedback requirements

ID	Requirement	Acceptance criterion
FR-07	Reflect engineering progress.	Status changes update the linked support request. Resolved means ready for customer confirmation, not released or customer-closed.
FR-08	Prepare an operations digest.	Morning/evening views use current session work, priorities, owners and blockers.
FR-09	Record recommendation feedback.	Track the latest decision per reviewed request, including priority, routing and summary changes. Seeded work is not counted as a new review.
FR-10	Make reset behavior explicit.	Reset restores the fictional scenario after confirmation. Refresh also resets the session.

Key user stories

As a...	I want to...	So that...
Support reviewer	Return a request with a note	The next reviewer knows what information is missing.
Engineering lead	Change queue or owner before approval	Responsibility is explicit rather than inferred from a score.
QA reviewer	Inspect suggested validation ideas	I can challenge whether the handoff is testable.
Technical Project Manager	See linked status and blockers	I can identify where coordination is needed.

Non-functional considerations

Use keyboard-accessible controls, labeled inputs and responsive layouts. Keep relative links compatible with GitHub Pages. Do not transmit credentials or user-entered text to a service. Make synthetic confidence, fictional workload and session-only storage explicit.

Future scope and validation

A production plan would need secure adapters, authorization, persistence, durable audit, redaction and evaluated model access. I would validate the workflow first. The UAT plan defines representative scenarios; it is not production acceptance or stakeholder sign-off.
