

Workflow & Architecture

Purpose: show where assistance prepares context and where a person makes the handoff decision.

Author: Jalpa Parmar

Version 1.0 | 23 September 2026

Independent portfolio prototype. Synthetic scenario; no employer or customer data.

AI prepares the context. A person reviews the recommendation before engineering work is created.

In the demo, context review and routing confirmation share one form. Approval is the final gate. People retain escalation and release decisions.

Technical view

Conceptual production flow. External platforms and adapters are not connected in this portfolio demo.

Stage	Responsibility
Support Platform	Receive a request and retain its source reference.
Integration / Normalization	Map and validate fields; minimize sensitive data before analysis.
Analysis Engine	Prepare context and recommendations for review.
Human Review	Edit context, confirm impact and ownership, approve or return.
Work Management	Maintain the approved item and engineering status.
Status / Reporting	Reflect progress and prepare operational views.

What the portfolio implements

I kept the demo intentionally simple: static web technology, synthetic data and deterministic rules. Decisions remain in memory for the session. No real model, external platform or production database is used.

Before a production implementation

Secure integrations, authentication and role-based access, persistent storage, durable audit logging, sensitive-data controls and evaluated model access would be required. Integration retries and duplicate prevention would need tests across systems, not only within a browser session.

Human review principle

Priority and routing are suggestions. A reviewer can change them, edit the summary or request more information. Engineering resolution does not approve a release or confirm the customer issue is closed.
